

Christmas Holiday Period Traffic Fatality Estimate, 2011

Prepared by
Statistics Department
National Safety Council
December 5, 2011

Holiday period definition

Christmas is December 25 and it is observed on that day. The length of the holiday period varies depending on what day of the week December 25 falls. It may be 1.25 days long if December 25 falls on a Wednesday; 3.25 days long if December 25 falls on a Friday, Saturday, Sunday, or Monday; or 4.25 days long if December 25 falls on a Tuesday or Thursday.

In 2011, Christmas falls on Sunday so the holiday period is 3.25 days and extends from 6:00 p.m. Friday, December 23, to 11:59 p.m. Monday, December 26.¹

Method and results

The objective is to estimate the number of deaths that will occur in traffic crashes during the Christmas holiday period based on data available several weeks before the holiday. The estimate developed here includes all traffic deaths from crashes that occur during the holiday period.²

The general procedure involves three steps. First, historical data are used to determine the average fraction holiday fatalities are of total deaths for the month containing the holiday. Second, total traffic deaths for the coming month in which the holiday falls are estimated using a time series forecasting model. Third, the projected total for the month is multiplied by the fraction to obtain the holiday estimate.

Holiday as percent of month. Total December deaths are the estimates published in *Injury Facts*[®] two years after the year of the estimate. This figure is used, rather than a revised estimate or the National Center for Health Statistics final count, because it closely approximates the level of accuracy that the time series estimate will give for total monthly deaths in the current year. Fatality Analysis Reporting System (FARS) data were used to obtain deaths during the holiday periods.

Table 1 shows the total traffic fatalities for the month of December and fatalities from crashes that occurred during the six most recent 3.25-day Christmas holiday periods. Fatalities from crashes during the Christmas holiday periods averaged 10.70% of the total fatalities in December.

Time series model and projection. A time series model was developed to forecast an estimate of total traffic deaths for December 2011. An Autoregressive Integrated Moving Average (ARIMA) model was constructed based on 48 months of traffic deaths recorded from November 2007 through October 2011. An ARIMA model was chosen because of the seasonal pattern in traffic deaths. The model was developed using the SPSS/PC+ Version 5.0 statistical computer package. The model forecasts total traffic fatalities for December 2011 to be 2,679.

Holiday estimate. Multiplying the projected total fatalities by the fraction obtained in the first step gives an estimate of 287 traffic fatalities from crashes during the holiday period.

Confidence interval

There is uncertainty associated with any estimate. The 90% confidence interval for the estimate of total December deaths is 2,420 to 2,965. If we assume that the fraction of December deaths that occur during the Christmas period is normally distributed, then the 90% confidence interval for that fraction is 9.08% to 12.33%. Combining these two gives the confidence interval for the Christmas period estimate: 220 to 365 traffic deaths.

Medically consulted injuries

The National Safety Council has now adopted the concept of medically consulted injury to replace disabling injury as the measure of nonfatal injuries. A medically consulted injury is an injury serious enough that a medical professional was consulted. Based on the current medically consulted injury to death ratio of 100:1, and rounded to the nearest hundred, the estimate of the number of nonfatal medically consulted injuries that will result from crashes during the holiday period is 28,700 with a range of 22,000 to 36,500. Medically consulted injuries are not comparable to previous disabling injury estimates.

Holiday comparison

A frequently asked question is "How much more dangerous is travel over the Christmas holiday?" There are two aspects of this question that must be considered. First, compared to what? And, second, what about changes in the amount of driving?

For most holidays, we compare the holiday to periods of similar length before and after it. Because New Year's Day is exactly one week after Christmas, we chose to compare Christmas to periods of similar length one week and two weeks before it. Specifically, from 6:00 p.m. Thursday to 11:59 p.m. Sunday of the two weeks immediately before the Christmas holiday. Table 2 shows the fatality data from FARS for comparable weekends. The average number of traffic deaths during Christmas over those six years was 3.1% *lower* than the average number of traffic deaths during the comparison periods (376 vs. 388 deaths). The difference between these two means is, however, *not* statistically significant.

The second question concerns changes in the amount of travel, or exposure. We know of no data system that tracks changes in vehicle miles of travel by day of the year on a national basis. Lacking an objective measure of exposure change, we assume that travel is greater on holidays than on nonholidays. If this is in fact true, then with greater travel and fewer deaths, the risk of dying in a traffic crash during the Christmas holiday period is less than comparable nonholiday periods.

Arnold and Cerrelli (1987) also examined the variation in fatalities during holiday periods.³ They used FARS data for 1975-1985 to determine average daily fatalities for each day of the week in each month (e.g., Mondays in December). For the extended Christmas holiday period, they found that fatalities rose 18% on December 21, 29% on December 22, 40% on December 23, and 41% on December 24. Fatalities dropped on December 25-30 to about 15% below normal throughout the week.

Evaluation

Table 3 compares the actual FARS counts with the Council's estimates for all holidays for which data are available. Seventy-four of the 89 actual counts fall within the 90% confidence interval of the estimate.

Notes

1. The National Highway Traffic Safety Administration extends the holiday period to 5:59 a.m. the following morning in its published tabulations of holiday deaths.
2. This differs from holiday estimates published by the Council in 1991 and earlier years. Comparisons should *not* be made between the holiday data and estimates shown here and holiday data and estimates published in 1991 and earlier years.
