

Labor Day Holiday Period Traffic Fatality Estimate, 2016

Prepared by
Statistics Department
National Safety Council
August 8, 2016

Holiday period definition

Labor Day is observed on the first Monday in September. It is always a 3.25-day weekend consisting of Friday evening, Saturday, Sunday, and Monday. In 2016, the holiday period extends from 6:00 p.m. Friday, September 2, to 11:59 p.m. Monday, September 5.¹

Method and results

The objective is to estimate the number of deaths that will occur in traffic crashes during the Labor Day holiday period based on data available before the holiday. The estimate developed here includes all traffic deaths from crashes that occur during the holiday period.²

The procedure involves three steps. First, historical data are used to determine the average fraction holiday fatalities are of total deaths for the month containing the holiday. Second, total traffic deaths for September 2016 are estimated using a time series forecasting model. Third, the projected total for the month is multiplied by the fraction to obtain the holiday estimate.

Holiday as percent of month. Total September deaths are the estimates published in *Injury Facts* two years after the year of the estimate (e.g., the September 2014 estimate that was published in the 2016 edition of *Injury Facts*). This figure is used, rather than a revised estimate or the National Center for Health Statistics final count, because it closely approximates the level of accuracy that the time series estimate will give for total monthly deaths in the current year. Fatality Analysis Reporting System (FARS) data were used to obtain deaths during the holiday periods.

Table 1 shows the total traffic fatalities for the month of September and fatalities from crashes that occurred during the holiday period. Over the 6 years 2009-2014, fatalities from crashes during the Labor Day holiday period averaged 12.02% of the total fatalities in September.

Time series model and projection. A time series model was developed to forecast an estimate of total traffic deaths for September 2016. An Autoregressive Integrated Moving Average (ARIMA) model was constructed based on 48 months of traffic deaths recorded from July 2012 through June 2016. An ARIMA model was chosen because of the seasonal variations in traffic deaths. The model was developed using the SPSS/PC+ Version 6.1 statistical computer package. The model forecasts total traffic fatalities for September 2016 to be 3,641.

Holiday estimate. Multiplying the projected total fatalities for September 2016 by the fraction obtained in the first step gives an estimate of 438 traffic fatalities from crashes during the holiday period.

Confidence interval

There is uncertainty associated with any estimate. The 90% confidence interval for the estimate of total September deaths is 3,333 to 3,976. If we assume that the fraction of September deaths that occur during the Labor Day period is normally distributed, then the 90% confidence interval for that fraction is 11.64% to 12.40%. Combining these two gives the confidence interval for the Labor Day period estimate: 388 to 493 traffic deaths.

Medically consulted injuries

Based on the current medically consulted injury to death ratio of 115:1, and rounded to the nearest hundred, the estimate of the number of nonfatal medically consulted injuries that will result from crashes during the holiday period is 50,300 with a range of 44,600 to 56,700. Medically consulted injuries are injuries serious enough that a medical professional was consulted and they are not comparable to previous disabling injury estimates.

Holiday comparison

A frequently asked question is "How much more dangerous is travel over the Labor Day holiday?" There are two aspects of this question that must be considered. First, compared to what? And, second, what about changes in the amount of driving?

We chose to compare the holiday to periods of similar length before and after the holiday. Specifically, from 6:00 p.m. Friday to 11:59 p.m. Monday of the weeks immediately before and after the Labor Day weekend. Table 2 shows the fatality data from FARS for 2009 to 2014 for comparable weekends. The average number of traffic deaths during Labor Day over those six years is 5.7% higher than the average number of traffic deaths during the comparison periods (371 vs. 351 deaths). The difference between these two means is statistically significant at the .05 level.

The second question concerns changes in the amount of travel, or exposure. We know of no data system that tracks changes in vehicle miles of travel by day of the year on a national basis. Lacking an objective measure of exposure change, we assume that travel is greater on holiday weekends than on nonholiday weekends.

If the assumed travel increase exceeds 5.7%, then the risk of dying in a traffic crash during the Labor Day holiday period is less than during comparable nonholiday periods. If the travel increase is less than 5.7% or if travel is actually lower, then the risk of dying on the holiday is greater than during comparable periods.

Arnold and Cerrelli (1987) also examined the variation in fatalities during holiday periods.³ They used FARS data for 1975-1985 to determine average daily fatalities for each day of the week in each month (e.g., Mondays in September). For the Labor Day holiday period, they found that fatalities rose 35% on Labor Day and were 16% higher than normal on the following Tuesday.

Evaluation

Table 3 compares the actual FARS counts with the Council's estimates for all holidays for which data are available. One-hundred-twenty of the 139 actual counts fall within the 90% confidence interval of the estimate.

Notes

1. The National Highway Traffic Safety Administration extends the holiday period to 5:59 a.m. Tuesday morning in its published tabulations of holiday deaths. Operation C.A.R.E. begins the counting period at 12:01 a.m. Friday.
2. This differs from holiday estimates published by the Council in 1991 and earlier years. The estimating method described here is entirely different from the method used by the Council through 1991 when estimates were discontinued. Comparisons should *not* be made between the holiday data and estimates shown here and holiday data and estimates published in 1991 and earlier years.
