

Thanksgiving Holiday Period Traffic Fatality Estimate, 2017

Prepared by
Research and Statistics Department
National Safety Council
November 13, 2017

Holiday period definition

Thanksgiving is observed on the fourth Thursday in November. It is always a 4.25-day weekend consisting of Wednesday evening, Thursday, Friday, Saturday, and Sunday. In 2017, the holiday period extends from 6:00 p.m. Wednesday, November 22, to 11:59 p.m. Sunday, November 26.¹

Method and results

The objective is to estimate the number of deaths that will occur in traffic crashes during the Thanksgiving holiday period based on data available approximately six to eight weeks before the holiday. The estimate developed here includes all traffic deaths from crashes that occur during the holiday period.² The procedure involves three steps. First, historical data are used to determine the average fraction holiday fatalities are of total deaths for the month containing the holiday. Second, total traffic deaths for the coming month in which the holiday falls are estimated using a time series forecasting model. Third, the projected total for the month is multiplied by the fraction to obtain the holiday estimate.

Holiday as percent of month. Total November deaths are the estimates published in *Injury Facts*[®] two years after the year of the estimate. This figure is used, rather than a revised estimate or the National Center for Health Statistics final count, because it closely approximates the level of accuracy that the time series estimate will give for total monthly deaths in the current year. Fatality Analysis Reporting System (FARS) data were used to obtain deaths during the holiday periods.

Table 1 shows the total traffic fatalities for the month of November and fatalities from crashes that occurred during the holiday period. Over the 6 years 2011-2016, fatalities during the Thanksgiving holiday period averaged 12.62% of the total fatalities in November.

Time series model and projection. A time series model was developed to forecast an estimate of total traffic deaths for November 2017. An Autoregressive Integrated Moving Average (ARIMA) model was constructed based on 48 months of traffic deaths recorded from October 2013 through September 2017. An ARIMA model was chosen because of the seasonal variations in traffic deaths. The model was developed using the SPSS/PC+ Version 6.1 statistical computer package. The model forecasts total traffic fatalities for November 2017 to be 3,339.

Holiday estimate. Multiplying the projected total fatalities for November 2017 by the fraction obtained in the first step gives an estimate of 421 traffic fatalities from crashes during the holiday period.

Confidence interval

There is uncertainty associated with any estimate. The 90% confidence interval for the estimate of total November deaths is 3,169 to 3,509. If we assume that the fraction of November deaths that occur during the Thanksgiving period is normally distributed, then the 90% confidence interval for that fraction is 12.10% to 13.15%. Combining these two gives the confidence interval for the Thanksgiving period estimate: 383 to 461 traffic deaths.

Nonfatal injuries

Nonfatal injury is defined as medically consulted injuries and these are injuries serious enough that a medical professional was consulted. Medically consulted injuries are not comparable to previous disabling injury estimates. Based on the current medically consulted injury to death ratio of 115:1, and rounded to the nearest hundred, the estimate of the number of nonfatal disabling injuries that will result from crashes during the holiday period is 48,500 with a range of 44,100 to 53,100.

Holiday comparison

A frequently asked question is "How much more dangerous is travel over the Thanksgiving holiday?" There are two aspects of this question that must be considered. First, compared to what? And, second, what about changes in the amount of driving?

We chose to compare the holiday to periods of similar length before and after the holiday. Specifically, from 6:00 p.m. Wednesday to 11:59 p.m. Sunday of the weeks immediately before and after the Thanksgiving weekend. Table 2 shows the fatality data from FARS for 2011 to 2016 for comparable weekends. The average number of traffic deaths during Thanksgiving over those six years was 5.0% *lower* than the average number of traffic deaths during the comparison periods (393 vs. 413 deaths). The difference between these two means is *not* statistically significant.

The second question concerns changes in the amount of travel, or exposure. We know of no data system that tracks changes in vehicle miles of travel by day of the year on a national basis. Lacking an objective measure of exposure change, we assume that travel is greater on holiday weekends than on non-holiday weekends. If that is in fact true, then with greater travel and fewer deaths, the risk of dying in a traffic crash during the Thanksgiving holiday period is less than comparable non-holiday periods.

Arnold and Cerrelli (1987) also examined the variation in fatalities during holiday periods.³ They used FARS data for 1975-1985 to determine average daily fatalities for each day of the week in each month (e.g., Thursdays in November). For the Thanksgiving holiday period, they found that fatalities rose 42% on the Wednesday before Thanksgiving and were 19% higher than normal on Thanksgiving Day. Fatalities were normal on the Friday, Saturday, and Sunday following the holiday.

Evaluation

Table 3 compares the actual FARS counts with the Council's estimates for all holidays for which data are available. One-hundred-nine of the 131 actual counts fall within the 90% confidence interval of the estimate.

Notes

1. The National Highway Traffic Safety Administration extends the holiday period to 5:59 a.m. Monday morning in its published tabulations of holiday deaths. Operation C.A.R.E. begins the counting period at 12:01 a.m. Wednesday.
2. This differs from holiday estimates published by the Council in 1991 and earlier years. The estimating method described here is entirely different from the method used by the Council through 1991 when estimates were discontinued. Comparisons should not be made between the holiday data and estimates shown here and holiday data and estimates published in 1991 and earlier years.
