

Thanksgiving Holiday Period Traffic Fatality Estimate, 2014

Prepared by
Research and Statistics Department
National Safety Council
November 6, 2014

The 2014 Thanksgiving Day holiday period begins at 6:00 p.m., Wednesday, November 26, and ends at 11:59 p.m., Sunday, November 30. Our estimate of traffic fatalities for this 4.25-day holiday period is **418** deaths with a 90% confidence interval (C.I.) of **367** to **474** deaths. Nonfatal medically consulted injuries, i.e. injuries serious enough that a medical professional was consulted, are estimated at 44,700 with a range of 39,300 to 50,800. The Thanksgiving Day holiday period is always 4.25 days in length. The estimated fatality total for 2014 is 4% less than the average actual number of fatalities (437) that occurred during the previous six Thanksgiving Day holiday periods for which data are available. An evaluation of recent Thanksgiving Day holiday period estimates is presented in the table below.

Evaluation of Recent Thanksgiving Day Holiday Period Estimates

Year	Estimate	90% Confidence Interval	Actual
2007	564	499-635	542
2008	479	415-551	484
2009	447	392-508	401
2010	441	378-513	417
2011	434	368-509	375
2012	451	384-528	405

Studies have shown that seat belts, when used, are 45% effective in preventing fatalities among front-seat passenger car occupants. Although the reduction in the risk of fatal injury from wearing seat belts is higher for light-truck occupants at 50%, the lower figure for passenger car occupants is used in the calculations here as the more conservative measure. The most recent data from the Fatality Analysis Reporting System (FARS) indicate that seat belt use by fatally injured passenger car and light truck occupants was 44.7%. Based on this information it is estimated that **153** person's lives may be saved this Thanksgiving Day holiday period because they will wear their safety belts and an additional **104** lives could be saved if all wore safety belts.

The average number of traffic fatalities during the six most recent Thanksgiving Day holiday periods was 1.2% *higher* than similar non-holiday periods (437 vs. 432 deaths). The difference is not statistically significant.

The terms used in the above discussion were chosen carefully to reflect the level of accuracy of the quantities involved. *Estimate* is used because the fatality figures are calculated approximately, as opposed to the precision of calculation inferred by the use of the word *predict*. *May* is used to indicate the figures express a contingency, whereas *will* is used to express something that may be expected or is supposed to occur.

Details of the estimating methodology and a discussion of holiday deaths compared to non-holiday periods are included in the following pages.

Holiday period definition

Thanksgiving is observed on the fourth Thursday in November. It is always a 4.25-day weekend consisting of Wednesday evening, Thursday, Friday, Saturday, and Sunday. In 2014, the holiday period extends from 6:00 p.m. Wednesday, November 26, to 11:59 p.m. Sunday, November 30.¹

Method and results

The objective is to estimate the number of deaths that will occur in traffic crashes during the Thanksgiving holiday period based on data available approximately six to eight weeks before the holiday. The estimate developed here includes all traffic deaths from crashes that occur during the holiday period.² The procedure involves three steps. First, historical data are used to determine the average fraction holiday fatalities are of total deaths for the month containing the holiday. Second, total traffic deaths for the coming month in which the holiday falls are estimated using a time series forecasting model. Third, the projected total for the month is multiplied by the fraction to obtain the holiday estimate.

Holiday as percent of month. Total November deaths are the estimates published in *Injury Facts*[®] two years after the year of the estimate. This figure is used, rather than a revised estimate or the National Center for Health Statistics final count, because it closely approximates the level of accuracy that the time series estimate will give for total monthly deaths in the current year. Fatality Analysis Reporting System (FARS) data were used to obtain deaths during the holiday periods.

Table 1 shows the total traffic fatalities for the month of November and fatalities from crashes that occurred during the holiday period. Over the 6 years 2007-2012, fatalities during the Thanksgiving holiday period averaged 14.15% of the total fatalities in November.

Time series model and projection. A time series model was developed to forecast an estimate of total traffic deaths for November 2014. An Autoregressive Integrated Moving Average (ARIMA) model was constructed based on 48 months of traffic deaths recorded from October 2010 through September 2014. An ARIMA model was chosen because of the seasonal variations in traffic deaths. The model was developed using the SPSS/PC+ Version 6.1 statistical computer package. The model forecasts total traffic fatalities for November 2014 to be 2,953.

Holiday estimate. Multiplying the projected total fatalities for November 2014 by the fraction obtained in the first step gives an estimate of 418 traffic fatalities from crashes during the holiday period.

Confidence interval

There is uncertainty associated with any estimate. The 90% confidence interval for the estimate of total November deaths is 2,748 to 3,173. If we assume that the fraction of November deaths that occur during the Thanksgiving period is normally distributed, then the 90% confidence interval for that fraction is 13.35% to 14.95%. Combining these two gives the confidence interval for the Thanksgiving period estimate: 367 to 474 traffic deaths.

Nonfatal injuries

Nonfatal injury is defined as medically consulted injuries and these are injuries serious enough that a medical professional was consulted. Medically consulted injuries are not comparable to previous disabling injury estimates. Based on the current medically consulted injury to death ratio of 107:1, and rounded to the nearest hundred, the estimate of the number of nonfatal disabling injuries that will result from crashes during the holiday period is 44,700 with a range of 39,300 to 50,800.

Holiday comparison

A frequently asked question is "How much more dangerous is travel over the Thanksgiving holiday?" There are two aspects of this question that must be considered. First, compared to what? And, second, what about changes in the amount of driving?

We chose to compare the holiday to periods of similar length before and after the holiday. Specifically, from 6:00 p.m. Wednesday to 11:59 p.m. Sunday of the weeks immediately before and after the Thanksgiving weekend. Table 2 shows the fatality data from FARS for 2006 to 2011 for comparable weekends. The average number of traffic deaths during Thanksgiving over those six years was 1.2% higher than the average number of traffic deaths during the comparison periods (437 vs. 432 deaths). The difference between these two means is *not* statistically significant.

The second question concerns changes in the amount of travel, or exposure. We know of no data system that tracks changes in vehicle miles of travel by day of the year on a national basis. Lacking an objective measure of exposure change, we assume that travel is greater on holiday weekends than on nonholiday weekends.

If travel increases by more than 1.2%, then the risk of dying on the holiday is less than during comparable periods. If the travel increase is less than 1.2%, or if travel is actually lower, then the risk of dying in a traffic crash during the Thanksgiving holiday period is greater than during comparable nonholiday periods.

Arnold and Cerrelli (1987) also examined the variation in fatalities during holiday periods.³ They used FARS data for 1975-1985 to determine average daily fatalities for each day of the week in each month (e.g., Thursdays in November). For the Thanksgiving holiday period, they found that fatalities rose 42% on the Wednesday before Thanksgiving and were 19% higher than normal on Thanksgiving Day. Fatalities were normal on the Friday, Saturday, and Sunday following the holiday.

Evaluation

Table 3 compares the actual FARS counts with the Council's estimates for all holidays for which data are available. Ninety-two of the 107 actual counts fall within the 90% confidence interval of the estimate.

Notes

1. The National Highway Traffic Safety Administration extends the holiday period to 5:59 a.m. Monday morning in its published tabulations of holiday deaths. Operation C.A.R.E. begins the counting period at 12:01 a.m. Wednesday.
2. This differs from holiday estimates published by the Council in 1991 and earlier years. The estimating method described here is entirely different from the method used by the Council through 1991 when estimates were discontinued. Comparisons should not be made between the holiday data and estimates shown here and holiday data and estimates published in 1991 and earlier years.
